Abstract

This article investigates to what extent austerity-oriented measures introduced in the Portuguese health sector during the recent economic crisis were associated with changes in the public opinion on healthcare. We conducted multivariate regression analyses of cross-sectional, biannual data from the European Social Survey (2002–2015) for 13,271 individuals living in private households in Portugal. In line with our expectations, healthcare evaluations of the general population improved until 2010 but declined with the implementation of comprehensive austerity measures introduced under the Memorandum of Understanding after 2011. Healthcare evaluations of vulnerable social groups – older and retired individuals, individuals with poor health, low income and education – declined particularly strongly. In addition, differences in healthcare evaluations between more and less vulnerable social groups were more pronounced after 2011. Interestingly, healthcare evaluations of the general population and of some of the most vulnerable groups ‘recovered’ in 2015, when most of the Memorandum measures were implemented. Our findings contribute to the literature on the effects of austerity measures on welfare attitudes and stress the need to analyse the differential impact of crisis-induced welfare state reforms across social groups.

1. Introduction

Welfare states face increasing pressure to reform in the context of population ageing and new social risks. The recent economic crisis intensified these pressures, especially for those European governments faced with rising unemployment and growing public debt. In some cases, policy-makers embraced comprehensive reforms marked by external conditionality and austerity aimed at reducing public sector expenditures, including those dedicated to the welfare sector. While the character of these crisis-triggered welfare reforms has been subject to close analysis (see e.g. Farnsworth and Irving, 2011; Greve, 2014; Shahidi, 2015; Ronchi,

2018; Schneider and Devitt, 2018a), little is known about their impact on public opinion.

This article aims to fill this gap. It analyses the effects of healthcare reforms in the context of the recent economic crisis and subsequent austerity, on the public's evaluation of the Portuguese healthcare system. Portugal was hard hit by the crisis, with growing government debt, rising unemployment and financial instability. As a response, the government introduced a set of austerity measures but, as these failed to stop the crisis, in 2011, it signed a bailout agreement, the Memorandum of Understanding (MoU), with the 'Troika' – the European Central Bank, European Commission and International Monetary Fund. Under the MoU, the Troika gave Portugal financial assistance in exchange for the implementation of a much more comprehensive set of austerity measures, extensively targeting the healthcare sector. In this study, we investigate whether Portuguese public opinion on healthcare has been responsive to these austerity measures and whether opinions differ across social groups.

Understanding public opinion on healthcare in the context of economic crisis is relevant for several reasons. For one thing, it can serve as a litmus-test of welfare state performance. One of the key roles of the welfare state is to protect its citizens, especially the most vulnerable, from risks and uncertainties (Barr, 2001). The provision of and access to good quality medical care is crucial during economic crises to alleviate experiences of economic hardship, as these can have detrimental effects on health (Stuckler *et al.*, 2011, 2017; Schrecker and Bamba, 2015). Negative opinions on healthcare in the context of crisis could therefore suggest failures in a welfare state's performance at a time when its support is most needed. In addition, changes in healthcare evaluations can signal changes in the public mood. A decline in the image of healthcare, one of the largest welfare sectors, can suggest a general decline in perceptions of the welfare state, with possibly significant consequences for its legitimacy (see Vis *et al.*, 2011; Roosma *et al.*, 2013). How an economic crisis shapes opinions towards healthcare can be crucial for the future of the healthcare system and welfare programmes more generally. While the positive views can legitimate the status quo and function as a defence mechanism against radical reforms, negative views of the welfare state and its performance could indicate low acceptability of the existing welfare arrangements, paired with unfulfilled expectations of the welfare system, creating pressure for policy change (see Kohl and Wendt, 2004).

2. Public opinion on healthcare

Various factors influence public opinion on the performance of the healthcare system, such as institutional characteristics of the healthcare system or the demographic and socioeconomic characteristics of the individual (Mossialos, 1997; Kohl and Wendt, 2004; Wendt *et al.*, 2010; Missinne *et al.*, 2013; Borisova *et al.*,

2017; Popic and Schneider, 2018). On the one hand, high levels of (public) healthcare spending or generous supplies of healthcare services in the form of a high density of general practitioners (GPs) increase satisfaction with the health system. On the other hand, high levels of private spending in the form of out-of-pocket payments for medical goods and services contribute to public dissatisfaction. Research also shows that satisfaction with the healthcare system differs across population groups and is related to the respondent's demographic and socioeconomic background as this is connected to his or her specific needs, interests, values and expectations (Wendt *et al.*, 2010; Missinne *et al.*, 2013; Footman *et al.*, 2013; Borisova *et al.*, 2017). Generally speaking, women, the elderly, and individuals with low income and poor health are less satisfied with the healthcare system than men, the young and those with higher economic status and better health.

While studies show that healthcare evaluations are influenced by both the institutional characteristics of the healthcare system and the personal characteristics of the respondent, there are reasons to believe the influence of these two factors will be particularly salient in the context of economic crisis. Periods of deteriorating and unstable economic conditions generate unemployment, debt and financial strain, all of which have a strong adverse effect on health, with the most vulnerable being particularly affected (Kentikelenis *et al.*, 2011; Sakellarides *et al.*, 2014; Stuckler *et al.*, 2011, 2017). Crisis also often triggers policy reforms. During the recent economic crisis, health policy in many European countries, especially those hardest hit by the crisis, was dominated by austerity. Austerity generally implied cuts in public healthcare spending and the introduction of measures inspired by the 'new public management' approach, which aimed at cost-saving and increased efficiency in the financing and provision of healthcare delivered by the public sector. In some cases, these cuts were severe and caused significant changes in the healthcare systems' institutional organisation, with a concomitant impact on users' experience by, for example, increasing waiting times or shifting the costs of care onto patients (Mladovsky *et al.*, 2012; Karanikolos *et al.*, 2013; Pavolini and Guillén, 2013; Thomson *et al.*, 2014).

So far, the research on the economic crisis and its consequences for public opinion has focused on changes in normative attitudes, such as attitudes towards redistribution or the state's role in welfare provision (e.g. Blekesaune, 2007, 2013; Margalit, 2013). Studies have found that, for example, crisis phenomena such as lower employment rates and personal experience of economic hardship are associated with stronger support for redistribution and government responsibility for welfare provision. Even people who do not experience economic hardship show stronger support for redistribution if they are living in countries where many other people report economic hardship (Blekesaune, 2013), a finding that emphasises the contextual dimension of welfare attitudes. While these

findings are interesting, they do not explore public views towards the performance of the welfare state or its specific sectors during crisis. Although we know normative attitudes, such as expectations towards the government role in providing healthcare, are inversely related to the general evaluation of healthcare services (Schneider and Popic, 2018), we can only speculate on whether crisis and austerity also affected the views of the performance of the healthcare system in Portugal.

3. The Portuguese healthcare system in the context of crisis

3.1. The Portuguese healthcare system

The Portuguese healthcare system is a mix of a universal, tax-financed public system and a system financed by social and private insurance schemes. The universal, tax-financed system is based on the National Health Service (NHS) model of healthcare; it provides medical care to the whole population on the basis of residence but, like other NHS systems, it is characterised by long waiting times (Bentes *et al.*, 2004). Specific social groups can access and receive faster and better quality healthcare services through either social insurance or voluntary private health insurance schemes. Social insurance schemes, also known as healthcare ‘subsystems’ (*subsistemas*), cover specific occupational groups and allow their beneficiaries free choice of healthcare providers and use of private healthcare facilities (Pereirinha, 1995; see also Guillén, 2002; Bentes *et al.*, 2004).¹ Voluntary private insurance schemes are mostly available to high earners and employees of private companies; they too offer supplementary coverage that allows free provider choice and access to private facilities, permitting their beneficiaries to skip the long waiting times in the public healthcare sector (Bentes *et al.*, 2004; Thomson and Mossialos, 2007).² From a systemic point of view, the specific mix of public, social and private insurance has created a dual system in which the better-off enjoy privileged access and conditions of care, while the more vulnerable, such as the unemployed, the old, the poor, and the disabled, rely on public healthcare (see Pereirinha, 1995).

3.2. Changes in the Portuguese healthcare system in the context of the financial crisis

In early 2010, Portugal was hit by the global financial crisis. An initial series of reforms in response to the crisis were introduced in three austerity packages in 2010 that sought to bring down the fiscal deficit (Afonso *et al.*, 2015). Some of these reforms targeted the healthcare system. One replaced obligatory with voluntary enrolment in the largest social health insurance fund (*ADSE*). Another featured cuts aimed at public sector employees, and thus NHS workers, including freezes and reductions of salaries. However, not all measures implied cuts, as one increased tax deductions for private health insurance.

Nevertheless, the country's economic conditions progressively worsened and the Portuguese government sought rescue in May 2011 by signing the above-mentioned MoU with the Troika. Under the MoU, Portugal would be given external financial assistance worth €78 billion in exchange for a series of radical austerity reforms. In the healthcare sector, these implied drastic cuts expected to result in €668 million savings, achieved through the implementation of a comprehensive set of more than 30 measures (European Commission, 2011; see also Barros, 2012a, 2012b; Sakellarides *et al.*, 2014). Table 1 gives an overview of some of the main MoU measures. Compared to the initial crisis measures of the Portuguese government (2010–2011), those implemented after the MoU (2012–2015) were more comprehensive and targeted more intensively both the general population and specific social groups, suggesting a stronger impact on provision of and access to healthcare services.

One of the first measures aimed at reducing public spending for pharmaceuticals by introducing reference pricing and promoting generic medicines; this, in turn, led to a reduction in the price of medicine (Barros, 2012c). Another measure involved increases in out-of-pocket payments through significant increases (in some cases, more than 100 per cent) in user fees (*taxas moderadoras*) for a wide range of health services, but specific social groups (e.g. children, the chronically ill) were exempted from these fees. Other austerity measures targeted the healthcare privileges of those with private and social insurance by eliminating tax deductions for private healthcare spending for the highest income categories, reducing tax deductions for spending on private healthcare insurance and increasing employee contributions to ADSE, the social health insurance for civil servants. The MoU measures also called for the continuation of previously introduced salary freezes and reductions for NHS staff but, at the same time, sought improvements in primary care by increasing the supply of family doctors.

The implementation of the MoU measures was coupled with severe cuts in healthcare spending. The total healthcare expenditure (THE, per capita) increased strongly, from €1584 in 2008 to €1671 in 2010, but decreased to €1480 in 2013. Then it rose again to €1557 in 2015. At the same time, public spending for healthcare (as % of THE) increased from 68.4 per cent in 2008 to 69.8 per cent in 2010; it decreased to 65.6 per cent in 2012 and had not fully recovered by 2015 (66.2 per cent). At the same time, out-of-pocket (OOP) spending (as % of THE) was lowest in 2010 at 24.6 per cent but increased to 28.2 per cent in 2012. In 2015, it was still high, at 27.7 per cent of THE. The impact of the MoU measures was less evident in the supply of health services. While there were no changes in the density of hospital beds (beds per 1000 population), the density of GPs and specialists increased continuously between 2008 and 2015, rising from 1.8 to 2.4 and from 1.9 to 2.3 (per 1000 population) for GPs and specialists respectively (OECD, 2017). This suggests that, as intended,

TABLE 1. Austerity measures introduced in the Portuguese healthcare systems during the crisis

Policy theme	Policy provision	Law	Introduction date	Implementation date
Healthcare subsystems	Enrolment in ADSE (subsystems for civil servants) becomes optional.	Law no. 3-B/2010	28/04/2010	29/04/2010
Private insurance	Introduction of 30% tax deduction for private healthcare insurance.	Law no. 55-A/2010	31/12/2010	01/01/2011
NHS staff	Salary freezes and reductions, stop on promotions, reductions of existing staff and new hirings, of overtime hours, of amounts paid for overtime work and of retirement benefits for public sector workers.	Law no. 55-A/2010	31/12/2010	01/01/2011
	Signing of the Memorandum of Understanding on 17 May 2011			
Pharmaceuticals	Introduction of external reference pricing. Price reduction of generic medicines: setting of the maximum price of the generic drug at least 50% lower than the price of the branded product with similar substance.	Decree-law no. 112/2011	29/11/2011	01/01/2012
User fees	Increase of user fees: consultation of general and family medicine or consultation other than specialty - €5,00 (increase from €2.25); consultation of nursing or consultation carried out in primary health care - €4.00; consultation of nursing or other consultation performed in the hospital - €5.00; specialty consultation - €7.50 (increase from €4.60); consultation at home - €10.00; medical consultation without the presence of the user - €3.00; multipurpose emergency service - €20.00 (increase from €9.60); emergency medical service - surgical - €17.50 (increase from €8.60); basic urgency service - €15.00 (increase from €8.60); permanent or extended care service - €10.00 (increased from €3.80). Revisions of user fees exemptions: exempted categories include pregnant women, children under 12, disabled, individuals below certain income threshold (average monthly income less than or equal to €628.83), blood and organ donors, transplant recipients, patients with chronic disorders, firefighters and military personnel.	Decree-Law no. 113/2011	29/11/2011	01/01/2012

TABLE 1. Continued

Policy theme	Policy provision	Law	Introduction date	Implementation date
Private healthcare spending	Elimination of tax deductions for private healthcare spending for the top two income brackets. Reduction of tax deductions for private health insurance spending from 30% to 10%.	Law no. 64-A/2011	30/12/2011	04/01/2012
User fees	Revisions of user fees exemptions: unemployed added as exempted category.	Law no. 128/2012	21/06/2012	22/06/2012
Health subsystems	Increase of employee contribution for the social health insurance from 1.5 to 2.25% of the salary. For pensioners, contribution for social health insurance set at 2.5% of the pension.	Decree-Law no. 105/2013	30/07/2013	31/07/2013
Healthcare subsystems	Further increase in employees contributions for social health insurance to 3.5% of the salary.	Law no. 30/2014	19/05/2014	20/05/2014
NHS staff	Continuation of salary freezes and reductions, stop on promotions and other saving measures concerning the public sector workers. Introduction of performance bonuses or other cash benefits of a related nature.	Law no. 82-B/2014	31/12/2014	01/01/2015
Primary care	Increasing the number of Family Health Units (<i>Unidades de Saúde Familiar</i>) and setting-up a mechanism to guarantee the presence of family doctors in needed areas to induce a more even distribution.	Decree-Law no. 223/2015	08/10/2015	09/10/2015

the austerity measures mainly affected healthcare spending, especially spending by public sources and out-of-pocket spending, while the supply of healthcare services remained unaffected or increased.

3.3. Access to healthcare in the context of crisis

Studies show that, with the implementation of the Troika's austerity measures, the Portuguese population had difficulties accessing care. Waiting times for the most common procedures, such as cataract surgery, decreased until 2011 but started to increase again in 2012 (OECD, 2017). Evidence also shows a decrease in the number of GP appointments and an increase in the number of missed NHS appointments (Sakellarides *et al.*, 2014). An increased share of the population had unmet healthcare needs for cost reasons following the implementation of the MoU (Eurostat, 2017).

Further, despite the measures intended to protect the most vulnerable, such as user fee exemptions, studies on the experiences of different social groups within the Portuguese healthcare system suggest the austerity effect was particularly strong for some of the most vulnerable social groups. Increases in user fees for primary and hospital care and difficulties in the implementation of exemptions may explain why accessibility to healthcare and medication deteriorated for elderly and chronically ill patients and had a negative effect for those living in disadvantaged areas (Legido-Quigley *et al.*, 2016; Costa *et al.*, 2017; Tavares and Zantomio, 2017). Additional evidence indicates the share of the population experiencing unmet healthcare needs for cost reasons after the MoU increased more dramatically for the lowest income quintile than for the highest income quintile (Eurostat, 2017). A similar trend is observed for unmet needs across age and gender groups; even though unmet needs increased for both subgroups, the increase was stronger for the older than for the younger, and for women than for men (Eurostat, 2017; see also Thomson *et al.*, 2014; Doetsch *et al.*, 2017).

4. Hypotheses

These findings allow us to speculate that the austerity measures introduced into the Portuguese healthcare system during the crisis had an effect on the healthcare evaluations of the general population and, more specifically, on the evaluations of particular social groups. The scope and degree of the austerity measures implemented under the MoU (after 2011) were much higher than the scope and degree of the initial crisis measures (until 2011) and more strongly affected users of public healthcare services. Lower total and public healthcare spending, increases in out-of-pocket payments for health services, and adverse experiences in gaining access to health services suggest public opinion towards the healthcare system was likely to be more negative after the implementation of the MoU measures. Thus, the effect of crisis on public evaluations of healthcare

services may only become visible after the implementation of the MoU measures. Specifically, we expect *healthcare evaluations of the Portuguese population to have dropped in 2012 after the implementation of the MoU measures (H1)*. However, whether the MoU measures had a long-lasting effect on public opinion towards healthcare remains an open empirical question. After 2012, total healthcare spending increased until 2015 and this may have had an ameliorative effect on opinion. That said, however, out-of-pocket payments (as % THE) remained high, and public health expenditure (as % THE) only slightly increased again suggesting a long-term effect of the crisis measures on public opinion, with healthcare evaluations kept correspondingly low.

Further, we expect the drop in healthcare evaluations in 2012 to be stronger for more vulnerable social groups, such as the old and non-employed, individuals with low income and education, and poor health status. As previously shown, these subgroups depend more strongly on the public NHS system and were more affected by the crisis. Thus, MoU measures, such as the introduction of user fees for NHS services, as well as cuts in public healthcare expenditure, had more severe consequences for them. We therefore expect to find *healthcare evaluations of individuals belonging to more vulnerable social groups, such as older and non-employed individuals, as well as those with low income, education, and health status, to have dropped more strongly in 2012 than the evaluations of those belonging to the more advantaged social groups (H2)*. At the same time, and as a direct consequence of Hypothesis 2, we expect *differences between healthcare evaluations of the more and the less vulnerable social groups would be more pronounced after the implementation of the MoU measures (H3)*.

5. Data and Methods

5.1. Data

The empirical analysis was based on the Portuguese sample of the European Social Survey (ESS), a high quality, cross-comparative data set providing biennial information representative of the European population aged 15 and above living in private households. The ESS follows a repeated cross-sectional design, and respondents are selected using strict probability sampling. Data were collected via face-to-face interviews. This study used all seven waves of the Portuguese sample of the ESS survey, covering a time span of 13 years (2002–2015). With the exception of round 7, fieldwork started in September/October of the indicated survey year and ended in the first months of the next calendar year. Response rates varied between rounds and ranged from 67 per cent in 2010/11 to 77 per cent in 2012/13.³ An exception is round 7, which was sampled in 2015, and had a response rate of only 43 per cent. In total, the Portuguese sample includes 13,271 individuals for whom information on all variables across years is available.

5.2. Variables

Evaluation of healthcare services was the main dependent variable in our analysis. In the survey, respondents were asked what they ‘think overall about the state of health services in their country nowadays’ on an 11-point scale ranging from 0 (extremely bad) to 10 (extremely good).

We measured changes in the evaluation of healthcare services using time dummy variables for each survey year. To explore subgroup differences in healthcare evaluations, we included respondents’ demographic and socio-economic characteristics, such as *sex/gender* (1 = female, 0 = male), *age* (<21, 21–35, 36–49, 50–64, 65+ years), and *migration background* (1 = born outside country of residence, 0 = born in country of residence). To test for *health needs*, we included two health variables: *self-reported health status* measured on a 5-point scale, ranging from very good to good, fair, bad, and very bad health; and health related *limitations in daily lives and routines* re-coded into a dummy variable (1 = a lot/to some extent, 0 = no limitations). Since information on household income is missing for wave 5 in the Portuguese dataset, we used a *subjective income variable* as a proxy for the financial resources available to the household. Survey respondents were asked how they ‘feel about their household income nowadays’ and whether they live comfortably on present income, cope on present income, find it difficult to live on present income, or find it very difficult to live on present income. We also included *current status of employment* (paid work, in education, unemployed, retired, disabled/long-term sick, and other employment status) and distinguished between *three educational groups*: respondents with completed lower secondary education or less (ISCED1/2, ‘lower educated’), those with upper secondary education and post-secondary non-tertiary education (ISCED 3/4, ‘middle educated’), and those with tertiary education (ISCED 5, ‘higher educated’). To control for other household-specific characteristics, we included *presence of a partner living in the household* (1 = yes, 0 = no), the *household size*, and whether *children are currently living in the household* (1 = yes, 0 = no).

We tested the sensitivity of our findings on healthcare services by comparing them to results on the evaluation of the state of education (see Schneider and Devitt, 2018b). This indicator has also been included in all seven rounds of the ESS and has been measured on a similar response scale. Respondents were asked what they think overall about the state of education in their country nowadays, on an 11-point scale ranging from 0 (extremely bad) to 10 (extremely good). An overview of the dependent and independent variables is provided in the supplementary online material (Table A1).

5.3. Methods

We applied ordinary least square (OLS) regression analysis with robust standard errors using the Huber-White-sandwich estimator. Changes in subgroup

differences across time were based on time-specific regression analysis for the following time periods: pre-crisis (2002–2007), the first crisis period (2008–2011), and the second crisis period which coincided with the implementation of the MoU measures (2012–2015) (see Table 2).⁴ To analyse the changes in healthcare evaluations for different population groups over time, we calculated interaction effects between subgroups and year of survey based on the pooled sample (2002–2015) (see Table 3). At all stages, we included demographic and socio-economic characteristics of the individual. To ensure representative estimations for the Portuguese population, we applied standard weights following the recommendations of the ESS. Note that we could not empirically test intra-individual changes in evaluations across time, as data are cross-sectional. Therefore, any assumptions as to causality remain speculative and require the inclusion of relevant indicators in longitudinal survey studies.

6. Results

6.1. Trends in healthcare evaluations for general population over time

Portuguese residents rated their healthcare services particularly low in 2002, with a mean of 3.30 (SD = 2.13). After that point, evaluations increased steadily, at least until 2010/11. Figure 1 gives an overview of changes in healthcare evaluations between 2010 and 2015, along with the major healthcare reforms introduced during this period. In 2010/11, evaluations reached a mean of 4.52 (SD = 2.17). With the signing of the MoU and the implementation of certain key austerity measures, evaluations dropped to a mean of 3.99 (SD = 2.28) in 2012/13. Despite the ongoing reform processes and the implementation of MoU measures until 2015, healthcare evaluations increased again in 2015 to 4.62 (SD = 2.56), slightly above the mean in 2010/11.

The results of the linear regression analysis support the above stated trends, even after controlling for standard demographic and socio-economic characteristics (Table 2, Model 1). Overall, healthcare evaluations increased gradually but significantly between 2002 and 2010. In 2010/11, evaluations were 1.27 scale points (SE = .10) higher than in 2002/03 and 0.28 scale points (SE = .08) higher than in 2008/09 (Table 3, Model 2). In line with Hypothesis 1, with the implementation of the MoU measures, evaluations dropped by 0.43 scale points (SE = .09) in 2012/13 from levels in 2010/11; they were even lower than in 2008/09 ($\beta = -.15$, SE = .08). Surprisingly, however, despite continued health policy interventions and crisis management after 2012, evaluations ‘recovered’ in 2015 and reached a level comparable to 2010/11.

6.2. Trends in healthcare evaluations for different subgroups over time

With the implementation of the MoU measures, healthcare evaluations dropped comparatively strongly for vulnerable and socially disadvantaged

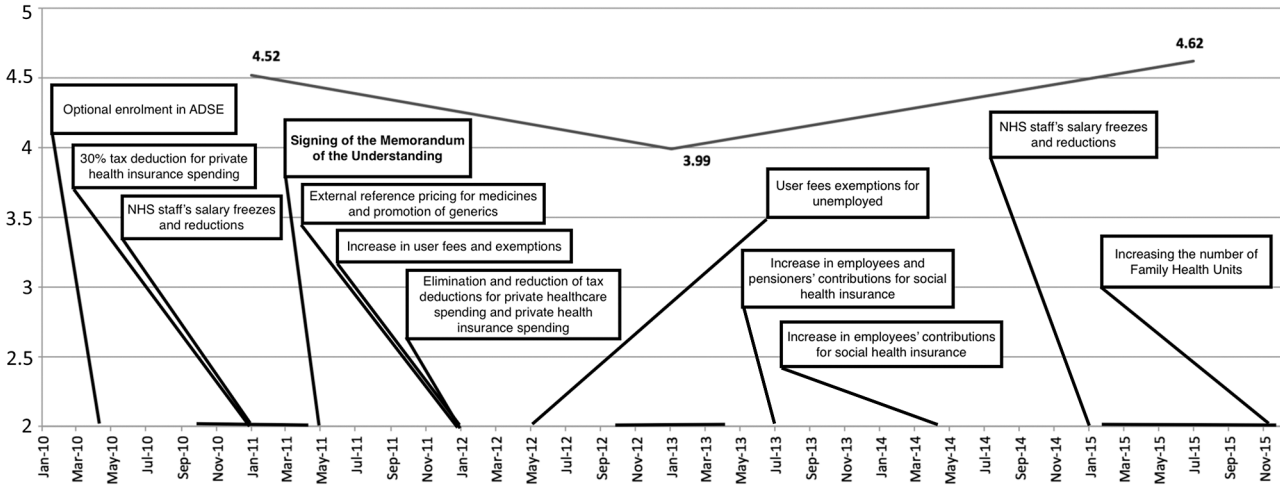

Figure 1 Evaluations of healthcare services and austerity measures in Portugal in the context of crisis

Note: The figure shows mean values of healthcare evaluations in Portugal for ESS waves 5 (2010/11), 6 (2012/13) and 7 (2015). Bold lines on the x-axis mark the periods of the European Social Survey fieldwork in Portugal.

groups (Table 3, model 2). More specifically, and in line with Hypothesis 2, compared to 2010/11, healthcare evaluations dropped in 2012/13 by 0.8 scale points for individuals age 65 and older ($\beta = -.77$, $SE = .16$) and for retirees ($\beta = -.79$, $SE = .15$). Those in fair, bad or very bad health rated healthcare services 0.7 scale points lower ($\beta = -.66$, $SE = .13$) in 2012/13 than in 2010/11, while those with good and very good health lowered their evaluations by only 0.3 scale points ($\beta = -.26$, $SE = .11$). Ratings of healthcare services dropped particularly strongly for those reporting difficulties living on their present income (difficult: $\beta = -.58$, $SE = .15$; very difficult: $\beta = -.73$, $SE = .28$), those with 'other employment status' (mostly house workers and respondents looking after children) ($\beta = -.82$, $SE = .29$), and the lower educated ($\beta = -.54$, $SE = .10$). In contrast, the evaluations of the more socially advantaged, e.g. individuals with higher education, income and those in paid employment, show only minor and insignificant changes between 2010/11 and 2012/13.

In line with the results reported for the general population, the healthcare evaluations of most subgroups 'recovered' in 2015 to the level of 2010/11 (Table 3, model 3). For example, those with 'other employment status' rated the healthcare system 1.3 scale points higher in 2015 than in 2012/13 ($\beta = 1.28$, $SE = .37$). Further, significant increases in healthcare evaluations between 2012/13 and 2015 are observed for the retired ($\beta = .77$, $SE = .21$) and individuals of 65 years of age and older ($\beta = .66$, $SE = .21$), those with health conditions limiting their daily activities ($\beta = .45$, $SE = .12$), those with lower education ($\beta = .53$, $SE = .13$), and those facing difficulties on their present income (difficult on present income: $\beta = .54$, $SE = .20$; very difficult on present income: $\beta = .76$, $SE = .32$).

There are exceptions to this trend, however. For example, the healthcare ratings of individuals with (fairly) bad health did not recover fully, at least until 2015. Notably, those reporting to be long-term sick or disabled evaluated

healthcare services very negatively in 2015, with ratings 1.4 scale points ($\beta = -1.36$, $SE = .73$) lower than in 2008/09, the pre-crisis period.

6.3. Trends in healthcare evaluations: differences between subgroups

Differences in subgroups' opinions of healthcare changed over time (Table 2, models 2–4). In line with Hypothesis 3, we find differences in the healthcare evaluations of groups with different health status and income were more pronounced after the implementation of the MoU measures. Firstly, with the implementation of the MoU measures, differences between *health groups* increased strongly, showing a very steep and gradual relationship between health status and healthcare evaluations in the second period of the economic crisis, i.e. between 2012 and 2015 (Table 2, model 4). Secondly, differences in healthcare evaluations between *income groups* became slightly stronger during the crisis, with those reporting difficulties living on their present household income more critical of the healthcare sector (Table 2, models 3/4).

Interestingly, we find a convergence in healthcare evaluations for specific groups despite initial differences before the economic crisis. For example, individuals with secondary education were more critical of health services than the lower educated before the economic crisis ($\beta = -.26$, $SE = .10$) and during the first crisis period ($\beta = .24$, $SE = .12$). But no significant differences between education groups were observed for the second period of the economic crisis ($\beta = .11$, $SE = .15$). Further, we find the younger and older age groups were more positive about Portuguese health services than the middle age groups. Interestingly, age differences were particularly strong in the period before the crisis but there were no significant differences between younger and middle-aged groups in the second period of the crisis.

6.4. Sensitivity check: evaluation of education system

To test whether our results are institution-specific and refer to actual changes in the healthcare sector, we repeated our analysis for evaluations of the education system (Table A3 in supplementary online material). Overall, the trends in perceptions of these two public institutions are different. We find that the evaluations of the education system increased gradually until 2010 and, unlike healthcare evaluations, remained rather stable thereafter. In contrast to healthcare evaluations, differences between age groups did not change during the crisis period. Contrary to our results for healthcare evaluations, both middle and higher educated groups were more negative about the education system than lower educated groups. At the same time, and similar to findings on healthcare evaluations, differences in evaluations of the education system were stronger between different income groups for the two crisis periods together (2008–2015) and between groups of different health status in the second crisis

period (2012–2015). In sum, these results show that ratings for health and education services differ. They strengthen the argument that attitudes are distinct and institution-specific and provide additional support for our findings on opinions of healthcare, proving our measurement to be sufficiently sensitive.

7. Summary and discussion

Previous research has indicated that public opinion on healthcare depends on the institutional structure of healthcare systems and individual characteristics connected to the interests and needs of particular subpopulations. Our study adds to the discussion by exploring changes in healthcare evaluations over time, using Portugal as an interesting test case. More specifically, we explored the effect of the economic crisis and the extent of austerity-oriented measures introduced in the Portuguese health sector on the public opinion towards healthcare. We began by examining the changes in legislation, healthcare spending, and access during the economic crisis and then empirically investigated changes in public opinion of the general population and specific groups using Portuguese data from the seven rounds of the European Social Survey (2002–2015).

In support of Hypothesis 1, we found healthcare evaluations steadily improved between 2002 and 2010 but dropped significantly in 2012/13 after the MoU. While this finding might not seem particularly surprising and complements previous research on the impact of institutional factors on public opinion (Wendt *et al.*, 2010; Jordan, 2010), it is significant. The crisis per se and the domestically crafted, relatively mild austerity measures introduced at the beginning of the crisis did not negatively affect the public opinion on healthcare. Instead, our findings suggest that external measures, conditioned by the Troika and marked by austerity, with more severe cuts in public healthcare spending, led to a more negative perception of the Portuguese health system.

Our findings also indicate that the policy changes introduced under the MoU affected social groups differently, and this is reflected in changes in the opinions of different groups over time. In support of Hypothesis 2, we found the decrease in healthcare evaluations in 2012 was more severe for more vulnerable groups, especially older groups, those with poor health, low income and education, the retired and non-employed. In contrast, only minor and insignificant changes were observable for groups with higher income and education, and those in paid work. Our findings support research showing that the austerity reforms introduced in the European healthcare sectors during the crisis, at least in the short term, had a stronger and more negative effect on the most vulnerable social groups (Stuckler *et al.*, 2011, 2017). Our findings also complement existing research on Portugal, which shows that the austerity-oriented health policies were associated with deteriorated access to medical services for the general population but had a more dramatic impact on vulnerable social groups

(Sakellarides *et al.*, 2014; Thomson *et al.*, 2014; Legido-Quigley *et al.*, 2016; Costa *et al.*, 2017). The findings suggest policy changes introduced under the MoU, such as cuts in total and public healthcare spending and an increase in out-of-pocket payments through increased user fees, despite exemptions, particularly affected the most vulnerable. The drop in the healthcare evaluations of these subgroups could be seen as a direct result of their healthcare experience (e.g. difficulties in accessing care) and/or reflect their disappointed expectation that the NHS would deliver care when it was most needed.

In addition, and in line with Hypothesis 3, differences in the healthcare evaluations of the more and the less vulnerable social groups increased in 2012/13. For example, we found differences between individuals of different health status were particularly strong after the implementation of the majority of the MoU measures. Similarly, we found more pronounced differences between income groups. This is relevant when we remember that the Portuguese healthcare system has a dual structure, privileging particular social groups, i.e. those with social and private health insurance who are usually better-off and less dependent on public health services. Therefore, our findings suggest that the austerity under MoU, which mainly targeted the public NHS system, accentuated the dual structure of the Portuguese system and affected more the most vulnerable subpopulations.

Interestingly, our findings show that evaluations worsened in 2012/13 only and improved thereafter, at least until 2015. This improvement in healthcare evaluations can be observed not only for the general population but also for the vulnerable groups, particularly those most affected by the economic crisis and changes in health policy measures, such as the old and retired, those with limitations in their daily activities due to health issues, and those with low income and education. This suggests that the MoU's austerity measures only had a short-term effect on the evaluations of the overall population and of the vulnerable groups. This could be explained by the gradual recovery of some of the healthcare system's key institutional characteristics, e.g. total healthcare spending, after the drop in 2012.

The timing of the specific MoU measures is another possible explanation of the trend in the evaluations. Most of the austerity measures, and some of the harshest ones such as increases in user fees, were implemented relatively shortly before the fieldwork of round 6 (2012/13) of the ESS. Between round 6 (2012/13) and round 7 (2015) fieldwork, the implemented measures targeted more specifically privileged social groups, i.e. those with social health insurance. The more vulnerable could see that others who were better off also had to accept cutbacks in their benefits (see Blekesaune, 2013), which could explain the improvement in the healthcare evaluations of the more vulnerable after 2012.

Other contextual, as well as psychological, factors might have played a role. It could be that the political and public discourse surrounding the

austerity reforms in Portugal, which often described these reforms as ‘necessary’ and ‘without alternative’ (see Moury and Standring, 2017), led the Portuguese to accept the inevitability of change. Despite their adverse experiences with the healthcare system, in the course of the crisis, they may have tried to adapt to the changes and reform processes. As expectations are inversely related to the evaluation of public services (Schneider and Popic, 2018), an adaptation of expectations towards the healthcare system may have led to the ‘recovery’ of healthcare evaluations in 2015. It seems equally reasonable that public opinion may have improved in 2015, when the MoU’s measures were almost completed, as the country had concluded the bailout agreement with the Troika. This may have generated relief and optimism among the Portuguese population.

However, and before any conclusions can be drawn from our results, we need to exclude any possible methodological reasons for our findings. The low response rate (43 per cent) and low sample size of the last round of the ESS in Portugal may have produced biased results. We used standard weights recommended by the ESS to correct for any biases; but more research, possibly in other survey studies, is clearly warranted to explore the validity of our findings, especially with respect to the recovery in healthcare evaluations in 2015.

7.1. Limitations

Admittedly, our results are not without limitations. Firstly, we were not able to observe utilisation patterns or barriers that may hinder access to health services. Therefore, our results do not allow us to make conclusions about the particular challenges respondents face when accessing health services and how they affect their general perception of health services. Secondly, we were only able to control for socio-economic characteristics that often serve as a rough proxy for the type of healthcare received by the respondent. No information on the respondents’ actual insurance status was available that was likely to have important implications for the perception of health services. The dual structure of the Portuguese healthcare system creates differences in healthcare access for different insurance types, and this changed during the crisis, possibly influencing perceptions of health services differently. Thirdly, we were not able to explore the respondents’ expectations of the healthcare system because we lacked appropriate data. Therefore, it remains speculative as to whether lower expectations of the government’s role in providing healthcare resulted in the ‘recovery’ in healthcare evaluations in 2015, or whether other factors triggered it. Lastly, and most importantly, we used cross-sectional data. This means any assumptions of causality must remain speculative; testing for intra-individual changes in evaluations across time would require the inclusion of relevant indicators in longitudinal survey studies.

8. Conclusion

The findings of our study suggest that the austerity measures introduced under the Troika's bailout agreement in Portugal during the recent economic crisis worsened public views towards healthcare, including those of the most vulnerable social groups. This has important implications for policymakers. Austerity may threaten the welfare state by preventing social policy programmes from performing one of their key functions – providing healthcare to the most vulnerable when it is most needed. The worsening of the views of the most vulnerable towards healthcare as one of the largest welfare sectors could suggest a more general worsening of the welfare state image in the eyes of its most likely beneficiaries, and this could have detrimental consequences for the legitimacy of the welfare state as a whole. Even though these measures did not have a prolonged negative effect, it is noteworthy that the Portuguese system belongs to the most critically perceived healthcare systems in Western Europe (Schneider and Devitt, 2018a). The fact that public opinion had 'recovered' by the time most of the MoU measures were implemented should not conceal the fact that the public's opinion towards healthcare is still comparatively low, indicating a general dissatisfaction among the Portuguese with their healthcare services before and after the economic crisis.

However, these implications are provisional. More research is needed to analyze the different effects of the economic crisis on the public opinion towards welfare in a comparative perspective, taking changes in the public's normative expectations towards the welfare system, especially healthcare, into account. Even though, in the recent crisis-triggered welfare state restructuring, other countries followed similar paths that seemed independent of their previous policy choices (see Shahidi, 2015), our research suggests that public views of the policy responses may depend on the country-specific structure of the welfare provision. This implies that similar government responses may affect public opinion very differently across countries. Further comparative analyses of the particular policy interventions, and their effects on the welfare views of both the general population and specific social groups, will provide a more refined picture of public perception of crisis management, leading to more specific policy advice.

Notes

- 1 The two main 'subsystems' (since 2005) are *ADSE (Assistência na Doença aos Servidores Cívicos do Estado)*, providing health insurance for civil servants and other public sector workers, and *ADM (Assistência na Doença aos Militares)*, an insurance scheme for military personnel. The subsystems are financed by employee contributions and general taxation.
- 2 In the early 2000s, around 25 per cent of the Portuguese population was covered by the subsystems (Bentes *et al.*, 2004), with about 15 per cent insured through private schemes (Guillén, 2002).
- 3 Wave-specific field work periods (FW), response rates (RR), and sample sizes (N) are as follows; wave 1: FW = 26.09.02–20.01.03, RR = 68.8 %, N = 1,458; wave 2: FW = 15.10.04–17.03.05, RR = 71.2 %, N = 1,972; wave 3: FW = 12.10.06–28.02.07, RR = 72.8 %; N = 2,095; wave 4: FW = 09.10.08–08.03.09, RR = 75.7 %, N = 2,295; wave 5: FW = 11.10.10–23.03.11, RR = 67.1 %, N = 2,100; wave 6: FW = 24.10.12–20.03.13, RR = 77.1 %, N = 2,113; wave 7: FW = 02.02.15–30.11.15, RR = 43 %, N = 1,238.
- 4 Results of the multivariate regression analysis for each year are reported in the online supplementary material, [Table A2](#).
